

CANONICAL CORRELATION

Problem Description

An analysis of the interrelations between two sets of variables measured on the same subjects is performed by this program. These variables are predictors in one set and criteria in the other set, but it is irrelevant whether the variables in the first set or in the second set are considered as the prediction variables. The canonical correlation, which gives the maximum correlation between linear functions of the two sets of variables, is calculated. χ^2 is also computed to test the significance of canonical correlation.

The sample problem for canonical correlation consists of four variables in the first set (left-hand side) and three variables in the second set (right-hand side) as presented in Table 6. These two sets of measurements have been made on 23 subjects.

Table 6. Sample Data for Canonical Correlation

Observation	First set				Second set		
	X ₁	X ₂	X ₃	X ₄	Y ₁	Y ₂	Y ₃

Program

Description

The canonical correlation program consists of the main routine named MCANO, a special input subroutine named DATA, and five subroutines from the Scientific Subroutine Package: CORRE, CANOR, MINV, NROOT, and EIGEN.

```

C      0 - IF IT IS NOT DESIRED

```

Capacity

The capacity of the sample program and the format required for data input have been set up as follows:

1. Up to 20 variables, including both the first set of variables (that is, left-hand variables) and the second set of variables (that is, right-hand variables) The number of variables in the first set must be greater than or equal to the number of variables in the second set.

2. Up to 99,999 observations

3. (12F6.0) format for input data cards

Therefore, if a problem satisfies the above conditions it is not necessary to modify the sample program. However, if there are more than 20 variables, dimension statements in the sample main program must be modified to handle the particular problem. Similarly, if input data cards are prepared using a different format, the input format in the input subroutine, DATA, must be modified. The general rules for program modification are described later.

Input

Control Card

One control card is required for each problem and is read by the main program, MCANO. This card is prepared as follows:

Columns	Contents	For Sample Problem
1 - 6	Problem number (may be alphameric)	SAMPLE
7 - 11	Number of observations	00023
12 - 13	Number of variables in the first set (that is, left-hand variables)*	04
14 - 15	Number of variables in the second set (that is, right-hand variables)	03

*The number of variables in the first set must be greater than or equal to the number of variables in the second set.

Leading zeros are not required to be keypunched.

Data Cards

Since input data are read into the computer one observation at a time, each row of data in Table 6 is keypunched on a separate card using the format (12F6.0). This format assumes twelve 6-column fields per card.

If there are more than twelve variables in a problem, each row of data is continued on the second

card until the last data point is keypunched. However, each row of data must begin on a new card.

Deck Setup

The deck setup is shown in Figure 47.

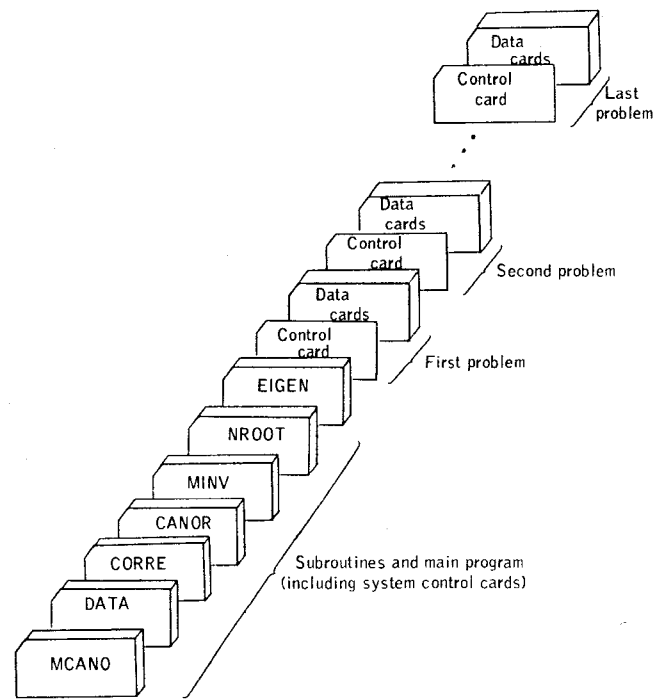

Figure 47. Deck setup (canonical correlation)

Sample

The listing of input cards for the sample problem is presented in Figure 48.

Output

Description

The output of the sample program for canonical correlation includes:

1. Means
2. Standard deviations
3. Correlation coefficients
4. Eigenvalues and corresponding canonical correlation
5. Lambda
6. Chi-square and degrees of freedom
7. Coefficients for left- and right-hand variables

Sample

The output listing for the sample problem is shown in Figure 49 of this sample problem.

Program Modification

Program capacity can be increased or decreased by making changes in dimension statements. Input data in a different format can also be handled by providing a specific format statement. In order to familiarize the user with the program modification, the following general rules are supplied in terms of the sample problem.

1. Changes in the dimension statements of the main program, MCANO:
 - a. The dimension of arrays XBAR, STD, CANR, CHISQ, and NDF must be greater than or equal to the total number of variables m ($m = p + q$, where p is the number of left-hand variables and q is the number of right-hand variables). Since there are seven variables, four on left and three on right, the value of m is 7.

Figure 49. Output listing (canonical correlation)

- b. The dimension of array RX must be greater than or equal to the product of $m \times m$. For the sample problem this product is $49 = 7 \times 7$.
- c. The dimension of array R must be greater than or equal to $(m + 1) m/2$. For the sample problem this number is $28 = (7 + 1)7/2$.
- d. The dimension of array COEFL must be greater than or equal to the product of $p \times q$. For the sample problem this product is $12 = 4 \times 3$.
- e. The dimension of array COEFR must be greater than or equal to the product of $q \times q$. For the sample problem this product is $9 = 3 \times 3$.

2. Changes in the input format statement of the special input subroutine, DATA:

Only the format statement for input data may be changed. Since sample data are either two- or three-digit numbers, rather than using six-column fields as in the sample problem, each row of data may be keypunched in seven 3-column fields, and, if so, the format is changed to (7F3.0).

The special input subroutine, DATA, is normally written by the user to handle different formats for different problems. The user may modify this subroutine to perform testing of input data, transformation of data, and so on.

Operating Instructions

The sample program for canonical correlation is a standard FORTRAN program. Special operating instructions are not required. Data set 5 is used for input, and data set 6 is used for output.

Timing

The execution time of this sample program on a System/360, Model 30, using an IBM 2540 Card Reader as input and an IBM 1403, Model 3 as output, is 19 seconds.
